

Using JavaScript with HTML

There are two ways to have our HTML recognize our JavaScript.

The first is by putting the code in internally to the HTML. You place the JavaScript code inside of `<script>` tags within the head section of your HTML.

```
<head>
  <meta charset="UTF-8">
  <title>JavaScript with HTML</title>
  <script>
    /* code goes here */
  </script>
</head>
```

Or you can place the code inside `<script>` tags after all the rest of the HTML right before the ending `</body>` tag.

```
    <script>
      /* code goes here */
    </script>
  </body>
</html>
```

The second way to have our HTML recognize our JavaScript is to put it in an external JavaScript file and reference that file from the `<script>` tag with a `src` or `source` attribute. This is like how we'd recognize a related CSS file. The `src` attribute would contain the path of where the JavaScript file is located. You need the correct path and the correct spelling of the existing JS file for the `src` value.

```
<head>
  <meta charset="UTF-8">
  <title>JavaScript with HTML</title>
  <script src="script.js" defer></script>
</head>
```

This can also be before the ending body tag as well.

```
<script src="script.js"></script>
</body>
</html>
```

Using external JS is considered best practice over internal JS

- It maintains a clean separation between HTML, CSS and JS
- It's easier to read, debug, and maintain
- The code in an external file can be reused across multiple pages
- and it reduced redundancy

The internal approach can still be useful for small, quick experiments or isolated cases where only a few lines of JavaScript are needed, but for most real-world applications, external files are the better choice.

So, there we have different ways to make sure your HTML recognizes the JavaScript that runs with it.
